EXTERNAL EXAMINER

ACKNOWLEDGEMENT

We express our deep gratitude to our respected Secretary and Correspondent **Dr.P.CHINNADURAI, M.A., Ph.D.**, for his kind words and enthusiastic motivation, which inspired us a lot in completing this project.

We would like to extend our heartfelt and sincere thanks to our Directors **Tmt.C.VIJAYA RAJESWARI, Dr.C.SAKTHIKUMAR, M.E.,Ph.D.,and Tmt. SARANYASREE SAKTHI KUMAR B.E., M.B.A.**, for providing us with the necessary facilities for completion of this project

We also express our gratitude to our Principal **Dr.K.Mani, M.E., Ph.D.**, for his timely concern and encouragement provided to us throughout the course.

We thank the HOD of CSE Department, **Dr. S.MURUGAVALLI , M.E.,Ph.D.**, for the support extended throughout the project.

We would like to thank my **Project Guide Mr. K. KAJENDRAN, M.C.A.,M.E.**, and all the faculty members of the Department of CSE for their advice and suggestions for the successful completion of the project.

NANTHAKUMAR J J.

PRAVEEN K.

NIRMAL KUMAR N.

ABSTRACT

Reviews act as a valuable source of information for decision-making. Online e-commerce sites have provided their users to make their opinion about products and services. A huge amount of such opinions are publicly available in the form of reviews. Manufacturers, retailers as well as customers have great interest in customer reviews. A customer has an interest in such reviews to determine which product or a particular brand to buy. Manufacturers can analyze the improvement area in their product from such opinionated reviews. Due to a large number of reviews available on the internet for analysis, it is not cost worthy to read these manually. To optimize this time-consuming task there is a need for an automated system that provides the summarized result of user sentiments. Opinion Mining (OM) in the field of study that analyzes people's sentiments or opinions from reviews or opinionated text. In the sentiment analysis process, machine learning is used to analyze sentiments, emotions and produce a summarized result for decision making. Opinion Mining can be viewed as a natural language processing task, the task is to develop a system that understands the people's language. Opinion Mining is a difficult task due to the ambiguous nature of human languages(like English). In this paper, we present a comprehensive study of sentiment analysis tasks and the challenges for the sentiment analysis system. As aspect-based sentiment analysis is an active research area in SA, we will cover this level of sentiment analysis in detail.

CHAPTER 1

INTRODUCTION

1.1 OVERVIEW

Natural Language Processing or NLP is a field of Artificial Intelligence that gives the machines the ability to read, understand and derive meaning from human languages.

It is a discipline that focuses on the interaction between data science and human language, and is scaling to lots of industries. Today NLP is booming thanks to the huge improvements in the access to data and the increase in computational power, which are allowing practitioners to achieve meaningful results in areas like healthcare, media, finance and human resources, among others.

USE CASES OF NLP

In simple terms, NLP represents the automatic handling of natural human language like speech or text, and although the concept itself is fascinating, the real value behind this technology comes from the use cases.

NLP can help you with lots of tasks and the fields of application just seem to increase on a daily basis. Let's mention some examples:

- NLP enables the recognition and **prediction of diseases** based on electronic health records and patient's own speech. This capability is being explored in health conditions that go from cardiovascular diseases to depression and even schizophrenia. For example, Amazon Comprehend Medical is a service that

uses NLP to extract disease conditions, medications and treatment outcomes from patient notes, clinical trial reports and other electronic health records.

- Organizations can determine what customers are saying about a service or product by identifying and extracting information in sources like social media. This **sentiment analysis** can provide a lot of information about customers choices and their decision drivers.
- Companies like Yahoo and Google filter and classify your emails with NLP by analyzing text in emails that flow through their servers and **stopping spam** before they even enter your inbox.
- To help **identifying fake news**, the NLP Group at MIT developed a new system to determine if a source is accurate or politically biased, detecting if a news source can be trusted or not.
- Amazon's Alexa and Apple's Siri are examples of intelligent **voice driven interfaces** that use NLP to respond to vocal prompts and do everything like find a particular shop, tell us the weather forecast, suggest the best route to the office or turn on the lights at home.

NLP is particularly booming in the **healthcare industry**. This technology is improving care delivery, disease diagnosis and bringing costs down while healthcare organizations are going through a growing adoption of electronic health records. The fact that clinical documentation can be improved means that patients can be better understood and benefited through better healthcare. The goal should be to optimize their experience, and several organizations are already working on this.

Basically, they allow developers and businesses to create a software that understands human language. Due to the complicated nature of human language, NLP can be difficult to learn and implement correctly. However, with the knowledge gained from this article, you will be better equipped to use NLP successfully, no matter your use case.

Natural language processing has a wide range of applications in business.

As just one example, brand sentiment analysis is one of the top use cases for NLP in business. Many brands track sentiment on social media and perform social media sentiment analysis. In social media sentiment analysis, brands track conversations online to understand what customers are saying, and glean insight into user behavior.

“One of the most compelling ways NLP offers valuable intelligence is by tracking sentiment — the tone of a written message (tweet, Facebook update, etc.) — and tag that text as positive, negative or neutral,” says Rehling.

Similarly, Facebook uses NLP to track trending topics and popular hashtags.

CHAPTER 2

LITERATURE SURVEY

TITLE SENTIMENT ANALYSIS ON TWITTER DATA

DESCRIPTION

Sentiment analysis is a type of natural language processing for tracking the mood of the public about a particular product or topic. Sentiment analysis, which is also called opinion mining, involves in building a system to collect and examine opinions about the product made in blog posts, comments, reviews or tweets. Sentiment analysis can be useful in several ways. In fact, it has spread from computer science to management sciences and social sciences due to its importance to business and society as a whole. In recent years, industrial activities surrounding sentiment analysis have also thrived. Numerous startups have emerged. Many large corporations have built their own in-house capabilities. Sentiment analysis systems have found their applications in almost every business and social domain. The goal of this report is to give an introduction to this fascinating problem and to present a framework which will perform sentiment analysis on online mobile phone reviews by associating modified K means algorithm with Naïve bayes classification and KNN.

TITLE Sentiment Analysis of Twitter Data using Machine Learning Approaches

DESCRIPTION

Twitter is a micro-blogging website that has become increasingly popular with the network community. Users update short messages, also known as Tweets, which are limited to 140 characters. Users update their personal opinions on many subjects, discuss current topics and write about life events through tweets. This platform is favored by many users because it has no political and economic restrictions and is easily available to large number of people. As the amount of users increase, micro-blogging platforms are becoming a place to find strong viewpoints and sentiment. People use twitter to forecast and analyze in a lot of different areas. For example, people have already forecasted the stock market success by using data from Twitter [7]. People use Twitter to forecast popularity and sales revenue of electronic products. From these case studies, we can know that Twitter is really useful for predicting products, services, or markets. It is one important reason why Twitter is taken into consideration to predict how people think about the popularity of day to day products. Another reason is because Twitter serves as a worthy platform for sentiment analysis due to its large user base with people across the world having different perspective. Twitter contains enormous amount of tweets, with millions being added every day. This can be easily collected through its APIs, which makes it easy to build a training set.

TITLE Twitter Data Analysis

DESCRIPTION The widespread and different types of information on Twitter make it one of the most appropriate virtual environments for information monitoring and tracking. In this paper, the authors review different information analysis techniques; starting with the analysis of different hashtags, twitter's network-topology, event spread over the network, identification of influence, and finally analysis of sentiment. Future research and development work will be addressed.

TITLE Sentiment Analysis Techniques Involving**DESCRIPTION**

Activities that take place or are influenced as a result of decisions being made are influenced by opinions at the root level. Analysis of opinions or sentiment analysis plays a vital role in trying to make as close approximation as possible. This is an extremely important aspect given that carefully planned and executed sentiment analyses can yield better and more accurate forecasts in politics as well as in business. At the base level, sentiment analysis stems from opinions shared or expressed by individuals and users. In the Internet space that permeates almost every known sphere and area of human activity on our planet, data in millions of bytes are posted and shared by individuals on social networking platforms, blogs, product review sites, and various other web forums. The potential to harvest such information and analyse the data can yield vital insights into how products, services, political personalities, companies, governments, etc. are perceived and viewed. Sentiment Analysis can engage multiple challenges such as accuracy-related issues, binary classification problem, data sparsity problem and

polarity shift. While there have been various methods that have been postulated and developed for sentiment analysis, there yet remains to be an efficient approach in extracting and producing accurate sentiment analysis on a consistent basis. Although machine learning algorithms have come a long way, with Naïve Bayes, Support Vector Machine and Maximum Entropy being the significant ones to feature prominently in research and mainstream use, sentiment classification by category involving positive and negative sentiments, is a topic of research interest in its own right. This paper presents a survey on prominent Sentiment Analysis approaches and methodologies and seeks to submit a clear evaluation report upon which grounds for further research can be based

CHAPTER 3

SYSTEM ANALYSIS

3.1 EXISTING SYSTEM

Twitter, with 500 million users and million messages per day, has quickly become a valuable asset for organizations to invigilate their reputation and brands by extracting and analyzing the sentiment of the tweets by the public about their products, services market, and even about competitors highlighted that, from the social media generated opinions with the mammoth growth of the world wide web, super volumes of opinion texts in the form of tweets, reviews, blogs or any discussion groups and forums are available for data analysis, thus making the world wide web the very fast, most comprising and easily accessible medium for Opinion Mining.

3.2 PROPOSED SYSTEM

Imagine you just launched a new product feature and notice a sharp increase in mentions on Twitter. Are customers tweeting more because they are delighted with the new feature? Or, are they actually complaining about the feature?

Going through each of these comments manually would take far too much time. You did miss out on valuable feedback that could help you instantly improve a customer's experience with the latest feature (bug issues, user experience).

By performing analysis with NLP, you can quickly understand the tone and context of social mentions on Twitter.

3.3 FEASIBILITY STUDY

A feasibility study is carried out to select the best system that meets performance requirements. The main aim of the feasibility study activity is to determine that it would be financially and technically feasible to develop the product.

3.3.1 TECHNICAL FEASIBILITY

This is concerned with specifying the software will successfully satisfy the user requirement. Open source and business-friendly and it is truly cross platform, easily deployed and highly extensible.

3.3.2 ECONOMIC FEASIBILITY

Economic analysis is the most frequently used technique for evaluating the effectiveness of a proposed system. The enhancement of the existing system doesn't incur any kind of drastic increase in the expenses. Python is open source and ready available for all users. Since the project is runned in python and jupyter notebook hence is cost efficient.

3.4 SYSTEM CONFIGURATION

3.4.1 HARDWARE CONFIGURATION

- Processor - Intel Core i3
- RAM - 4 GB
- Hard Disk - 500 GB

3.4.2 SOFTWARE CONFIGURATION

- Operating System - Windows 7/8/10
- Programming Language : Python 3.x
- Django, tweepy, textblob
- Twitter API Credentials
- Chartjs

3.5 SOFTWARE SPECIFICATION

3.5.1 NLP Analysis

Natural Language Processing (NLP) refers to AI method of communicating with an intelligent systems using a natural language such as English.

Processing of Natural Language is required when you want an intelligent system like robot to perform as per your instructions, when you want to hear decision from a dialogue based clinical expert system, etc.

The field of NLP involves making computers to perform useful tasks with the natural languages humans use. The input and output of an NLP system can be –

- Speech
- Written Text

Their application to Natural Language Processing (NLP) was less impressive at first, but has now proven to make significant contributions, yielding state-of-the-art results for some common NLP tasks. Named entity recognition (NER), part of speech (POS) tagging or sentiment analysis are some of the problems where neural network models have outperformed traditional approaches. The progress in machine translation is perhaps the most remarkable among all.

NLP is a tool for computers to analyse, comprehend, and derive meaning from natural language in an intelligent and useful way. This goes way beyond the most recently developed chatbots and smart virtual assistants. In fact, natural language processing algorithms are everywhere from search, online translation, spam filters and spell checking.

3.6 API

API is an abbreviation for Application Programming Interface which is a collection of communication protocols and subroutines used by various programs to communicate between them. A programmer can make use of various API tools to make its program easier and simpler. Also, an API facilitates the programmers with an efficient way to develop their software programs.

Thus in simpler terms, an API helps two programs or applications to communicate with each other by providing them with necessary tools and functions. It takes the request from the user and sends it to the service provider and then again sends the result generated from the service provider to the desired user.

A developer extensively uses API's in his software to implement various features by using an API call without writing the complex codes for the same. We can create an API for an operating system, database systems, hardware system, for a JavaScript file or similar object oriented files. Also, an API is similar to a GUI(Graphical User Interface) with one major difference. Unlike GUI's, an API helps the software developers to access the web tools while a GUI helps to make a program easier to understand by the users.

Real life example of an API:

Suppose, we are searching for a hotel room on an online website. In this case, you have a vast number of options to choose from and this may include the hotel location, the check-in and check-out dates, price, accommodation details and many more factors. So in order to book the room online, you need to interact with the hotel booking's website which in further will let you know if there is a room

available on that particular date or not and at what price.

Now in the above example, the API is the interface that actually communicates in between. It takes the request of the user to the hotel booking's website and in turn returns back the most relevant data from the website to the intended user. Thus, we can see from this example how an API works and it has numerous applications in real life from switching on mobile phones to maintaining a large amount of databases from any corner of the world.

There are various kinds of API's available according to their uses and applications like the Browser API which is created for the web browsers to abstract and to return the data from surroundings or the Third party API's, for which we have to get the codes from other sites on the web(e.g. Facebook, Twitter).

ADVANTAGES OF APIS

- **Efficiency:** API produces efficient, quicker and more reliable results than the outputs produced by human beings in an organization.
- **Flexible delivery of services:** API provides fast and flexible delivery of services according to developers requirements.
- **Integration:** The best feature of API is that it allows movement of data between various sites and thus enhances integrated user experience.
- **Automation:** As API makes use of robotic computers rather than humans, it produces better and automated results.
- **New functionality:** While using API the developers find new tools and functionality for API exchanges.

DISADVANTAGES OF APIS

- **Cost:** Developing and implementing API is costly at times and requires high maintenance and support from developers.
- **Security issues:** Using API adds another layer of surface which is then prone to attacks, and hence the security risk problem is common in API's.

3.6.1 END POINTS

What is an API Endpoint?

Simply put, an endpoint is one end of a communication channel. When an API interacts with another system, the touchpoints of this communication are considered endpoints. For APIs, an endpoint can include a URL of a server or service. Each endpoint is the location from which APIs can access the resources they need to carry out their function.

APIs work using 'requests' and 'responses.' When an API requests information from a web application or web server, it will receive a response. The place that APIs send requests and where the resource lives, is called an endpoint.

Why Are API Endpoints Important?

All over the world, companies leverage APIs to transfer vital information, processes, transactions, and more. API usage will only increase as time goes on, and making sure that each touchpoint in API communication is intact is vital to the success of each API. Endpoints specify where resources can be accessed by APIs

and play a key role in guaranteeing the correct functioning of the software that interacts with it. In short, API performance relies on its ability to communicate effectively with API Endpoints.

Do I Need to Monitor API Endpoints?

YES. Understanding how each API is performing can drastically change the way you're able to capture the value APIs add to your business. Proactively Monitoring APIs can ensure that you're able to find issues before real users experience them.

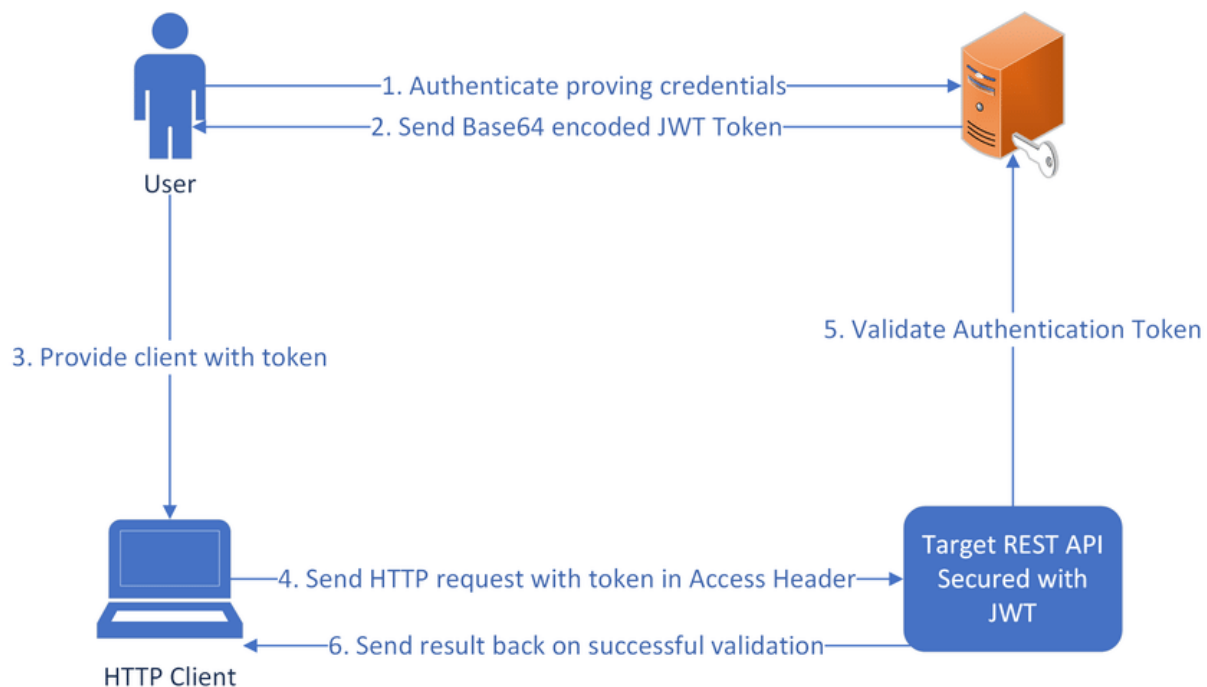

Fig 3.6.1 REST API

REST stands for REpresentational State Transfer and API stands for Application Program Interface. REST is a software architectural style that defines the set of rules to be used for creating web services. Web services which follow the REST architectural style are known as RESTful web services. It allows requesting

systems to access and manipulate web resources by using a uniform and predefined set of rules. Interaction in REST based systems happen through Internet's Hypertext Transfer Protocol (HTTP).

A Restful system consists of a:

- client who requests for the resources.
- server who has the resources.

It is important to create REST API according to industry standards which results in ease of development and increase client adoption.

3.7 VISUALIZATION

Data visualization is a way of exploring **complex patterns** or **large quantities** of data that cannot be easily perceived by looking at a table of numbers or reading paragraphs of text. The goal of data visualization is to communicate information more clearly, and it does so by employing our innate ability to recognize visual patterns in our environment.

Fig 3.7.1 Visualization Diagram

Some data visualizations are **exploratory** in that they are created before any analysis is done on the data. Looking at a visual representation of our dataset can give us clues about what to focus on during analysis.

Some data visualizations are **communicative** in that they are created in order to present our analysis findings to an audience. Using visual patterns to represent patterns in data can be an effective way of explaining complex results.

Ultimately, data visualizations can more effectively answer questions, tell stories and put forth arguments than words alone.

In the world of Big Data, data visualization tools and technologies are essential to analyze massive amounts of information and make data-driven decisions.

Our eyes are drawn to colors and patterns. We can quickly identify red from blue, square from circle. Our culture is visual, including everything from art and advertisements to TV and movies.

Data visualization is another form of visual art that grabs our interest and keeps our eyes on the message. When we see a chart, we quickly see trends and outliers. If we can see something, we internalize it quickly. It's storytelling with a purpose. If you've ever stared at a massive spreadsheet of data and couldn't see a trend, you know how much more effective a visualization can be.

Big Data is here and we need to know what it says

As the "age of Big Data" kicks into high-gear, visualization is an increasingly key tool to make sense of the trillions of rows of data generated every day. Data visualization helps to tell stories by curating data into a form easier to understand,

highlighting the trends and outliers. A good visualization tells a story, removing the noise from data and highlighting the useful information.

However, it's not simply as easy as just dressing up a graph to make it look better or slapping on the "info" part of an infographic. Effective data visualization is a delicate balancing act between form and function. The plainest graph could be too boring to catch any notice or it make tell a powerful point; the most stunning visualization could utterly fail at conveying the right message or it could speak volumes. The data and the visuals need to work together, and there's an art to combining great analysis with great storytelling.

Why data visualization is important for any career

It's hard to think of a professional industry that doesn't benefit from making data more understandable. Every STEM field benefits from understanding data—and so do fields in government, finance, marketing, history, consumer goods, service industries, education, sports, and so on.

While we'll always wax poetically about data visualization (you're on the Tableau website, after all) there are practical, real-life applications that are undeniable. And, since visualization is so prolific, it's also one of the most useful professional skills to develop. The better you can convey your points visually, whether in a dashboard or a slide deck, the better you can leverage that information.

Fig 3.7.2 Types Of Visualizations

The concept of the citizen data scientist is on the rise. Skill sets are changing to accommodate a data-driven world. It is increasingly valuable for professionals to be able to use data to make decisions and use visuals to tell stories of when data informs the who, what, when, where, and how. While traditional education typically draws a distinct line between creative storytelling and technical analysis, the modern professional world also values those who can cross between the two: data visualization sits right in the middle of analysis and visual storytelling.

CHAPTER 4

ARCHITECTURE

4.1 SYSTEM ARCHITECTURE

System architecture is the conceptual model that defines the structure, behavior, and more views of a system. An architecture description is a formal description and representation of a system, organized in a way that supports reasoning about the structures and behaviors of the system.

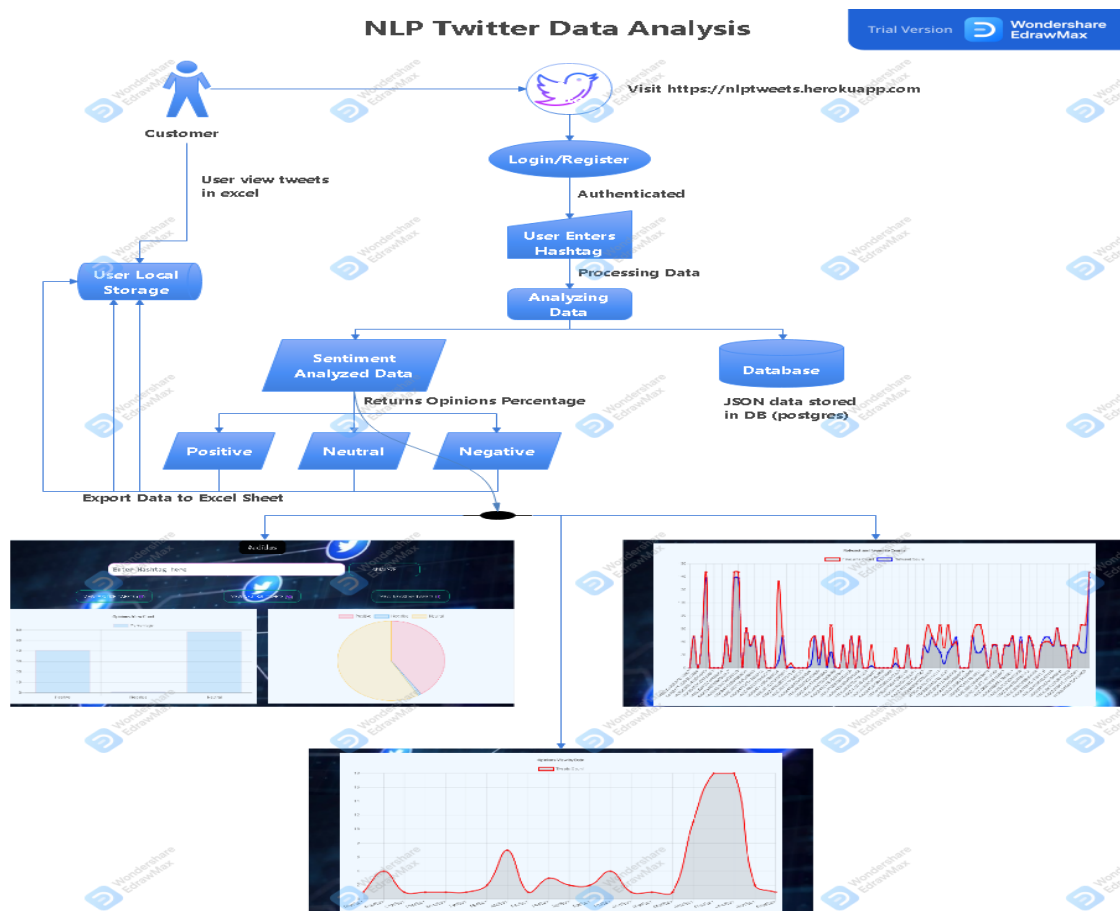

Fig 4.1.1 Architecture Diagram

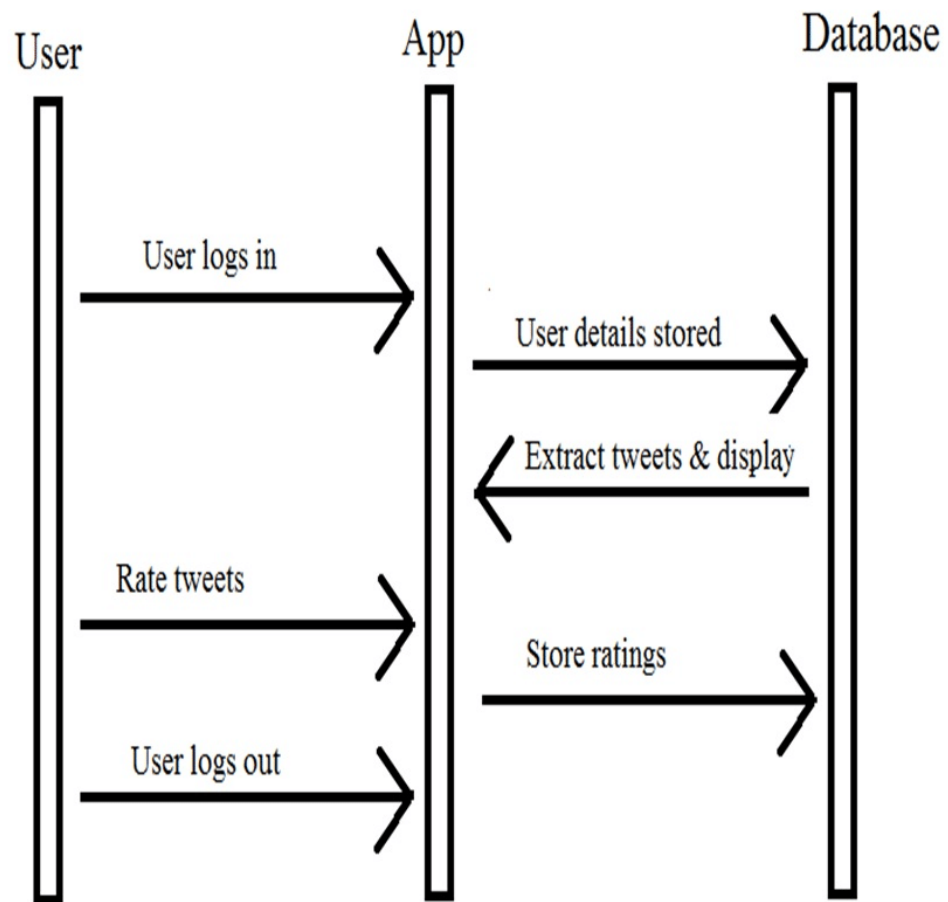

Fig 4.2.3 Sequence Diagram

4.2.4 STATE CHART DIAGRAM

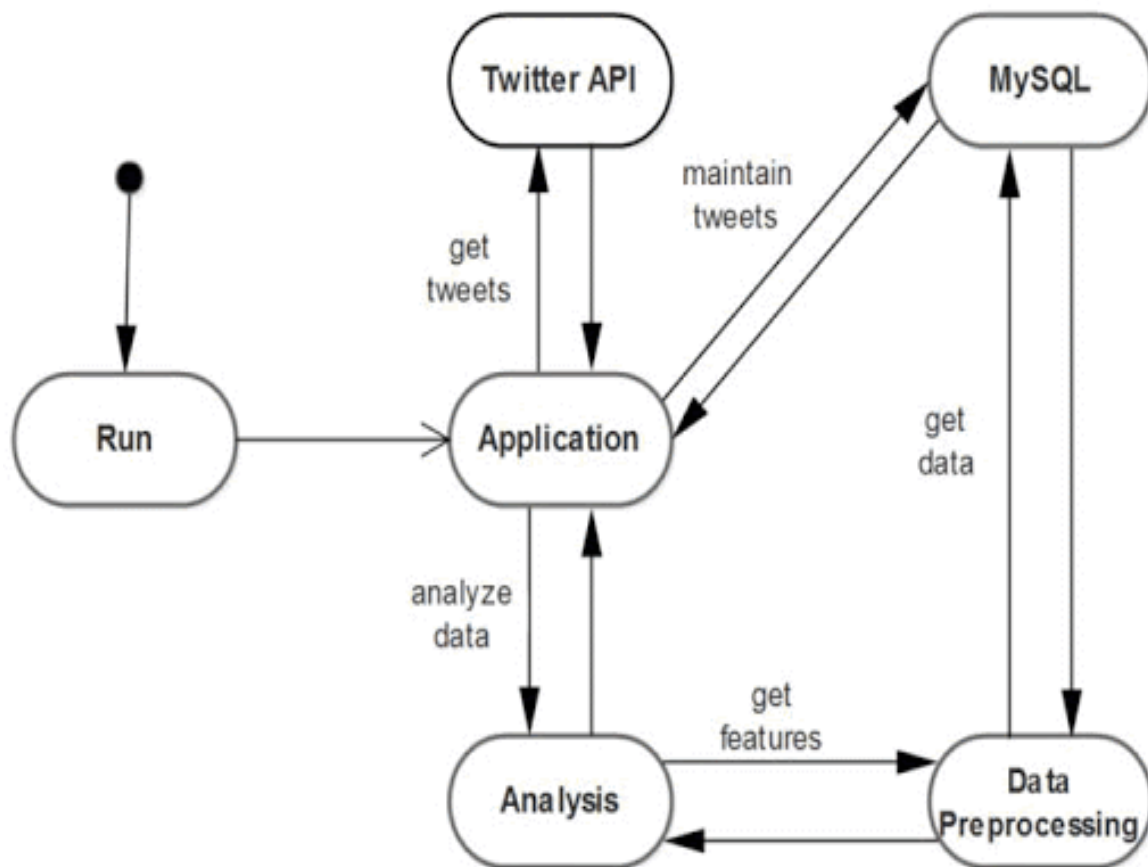

Fig 4.2.4 Statechart Diagram

CHAPTER 5

SYSTEM MODULE

5.1 MODULE

- Twitter Data Collection
- Data Preprocessing
- Text Blob

5.2MODULE DESCRIPTION

5.2.1 TWITTER DATA COLLECTION

Twitter is a gold mine of data. Unlike other social platforms, almost every user's tweets are completely public and pullable. This is a huge plus if you're trying to get a large amount of data to run analytics on. Twitter data is also pretty specific. Twitter's API allows you to do complex queries like pulling every tweet about a certain topic within the last twenty minutes, or pull a certain user's non-retweeted tweets.

A simple application of this could be analyzing how your company is received in the general public. You could collect the last 2,000 tweets that mention your company (or any term you like), and run a sentiment analysis algorithm over it.

Twitter's Developer Policy is generally interpreted as allowing sharing of tweets locally, i.e., within an academic institution. For example, we share the datasets we have collected at GW Libraries with members of the GW research community (but when sharing outside the GW community, we only share the tweet ids). However, only a small number of institutions proactively collect Twitter data – your library is a good place to inquire.

Another option for acquiring an existing Twitter dataset is TweetSets, a web application that I've developed. TweetSets allows you to create your own dataset by querying and limiting an existing dataset. For example, you can create a dataset that only contains original tweets with the term “trump” from the Women's March dataset. If you are local, TweetSets will allow you to download the complete tweet; otherwise, just the tweet ids can be downloaded. Currently, TweetSets includes nearly a half billion tweets.

We can also target users that specifically live in a certain location, which is known as spatial data. Another application of this could be to map the areas on the globe where your company has been mentioned the most.

As you can see, Twitter data can be a large door into the insights of the general public, and how they receive a topic. That, combined with the openness and the generous rate limiting of Twitter's API, can produce powerful results.

5.2.2 DATA PREPROCESSING

Data preprocessing is an important tool for Data Mining (DM) algorithm. Twitter data is an unstructured data set it is a collection of information from people entered his/her feelings, opinion, attitudes, products review, emotions, etc. This type of information is growing day by day in the internet. May companies want to analyze customers opinions which like the product and the services. The Proposed work to analyses the twitter trending information and collect various different information form the users. It improves the accuracy of Twitter data. This work easy to identify the people reaction or opinion. Additionally, improve the better performance for data preprocessing tool.

5.2.3 TEXTBLOB

TextBlob is a Python (2 and 3) library for processing textual data. It provides a simple API for diving into common natural language processing (NLP) tasks such as part-of-speech tagging, noun phrase extraction, sentiment analysis, classification, translation, and more.

Install TextBlob using the following commands in terminal:

```
pip install -U textblob
```

This will install TextBlob and download the necessary NLTK corpora. The above installation will take quite some time due to the massive amount of tokenizers, chunkers, other algorithms, and all of the corpora to be downloaded.

Some terms that will be frequently used are :

- **Corpus** – Body of text, singular. Corpora is the plural of this.
- **Lexicon** – Words and their meanings.
- **Token** – Each “entity” that is a part of whatever was split up based on rules. For examples, each word is a token when a sentence is “tokenized” into words. Each sentence can also be a token

So basically tokenizing involves splitting sentences and words from the body of the text.

The approach that the TextBlob package applies to sentiment analysis differs in that it’s rule-based and therefore requires a pre-defined set of categorized words. These words can, for example, be uploaded from the NLTK database. Moreover, sentiments are defined based on semantic relations and the frequency of each word in an input sentence that allows getting a more precise output as a result.

Fig 5.2.3 TextBlob Architecture Diagram

TextBlob's output for a **polarity** task is a float within the range $[-1.0, 1.0]$ where -1.0 is a negative polarity and 1.0 is positive. This score can also be equal to 0 , which stands for a neutral evaluation of a statement as it doesn't contain any words from the training set.

Whereas, a **subjectivity/objectivity** identification task reports a float within the range $[0.0, 1.0]$ where 0.0 is a very objective sentence and 1.0 is very subjective.

CHAPTER 6

SYSTEM DESIGN

6.1 TWITTER API CODING

```
import re

import tweepy

from tweepy import OAuthHandler

from textblob import TextBlob

class TwitterClient(object):

    """

    Generic Twitter Class for sentiment analysis.

    """

    def __init__(self):

        """

        Class constructor or initialization method.

        """

        # keys and tokens from the Twitter Dev Console
```

```

consumer_key = 'YOUR CONSUMER KEY'

consumer_secret = 'YOUR CONSUMER SECRET'

access_token = 'YOUR ACCESS TOKEN'

access_token_secret = 'YOUR ACCESS SECRET'

# attempt authentication

try:

    # create OAuthHandler object

    self.auth = OAuthHandler(consumer_key, consumer_secret)

    # set access token and secret

CHAPTER 7

SOFTWARE TESTING

7.1 INTRODUCTION

Testing is a process of executing a program with the intent of finding an error. A good test case is one that has a high probability of finding an as-yet – undiscovered error. A successful test is one that uncovers an as-yet- undiscovered error. System testing is the stage of implementation, which is aimed at ensuring that the system works accurately and efficiently as expected before live operation commences. It verifies that the whole set of programs hang together. System testing requires a test consists of several key activities and steps for run program, string, system and is important in adopting a successful new system. This is the last chance to detect and correct errors before the system is installed for user acceptance testing

7.2 TYPES OF TESTS

7.2.1 UNIT TESTING

Unit testing involves the design of test cases that validate that the internal program logic is functioning properly, and that program inputs produce valid outputs. All decision branches and internal code flow should be validated. It is the testing of individual software units of the application .it is done after the completion of an individual unit before integration. This is a structural testing, that relies on knowledge of its construction and is invasive. Unit tests perform basic

tests at component level and test a specific business process, application, and/or system configuration. Unit tests ensure that each unique path of a business process performs accurately to the documented specifications and contains clearly defined inputs and expected results.

7.2.2 INTEGRATION TESTING

Integration tests are designed to test integrated software components to determine if they actually run as one program. Testing is event driven and is more concerned with the basic outcome of screens or fields. Integration tests demonstrate that although the components were individually satisfaction, as shown by successfully unit testing, the combination of components is correct and consistent. Integration testing is specifically aimed at exposing the problems that arise from the combination of components.

7.2.3 FUNCTIONAL TEST

Functional tests provide systematic demonstrations that functions tested are available as specified by the business and technical requirements, system documentation, and user manuals.

Functional testing is centered on the following items:

Valid Input : identified classes of valid input must be accepted.

Invalid Input : identified classes of invalid input must be rejected.

Functions : identified functions must be exercised.

Output : identified classes of application outputs must be exercised

Systems/Procedures: interfacing systems or procedures must be invoked.

Organization and preparation of functional tests is focused on requirements, key functions, or special test cases. In addition, systematic coverage pertaining to identify Business process flows; data fields, predefined processes, and successive processes must be considered for testing. Before functional testing is complete, additional tests are identified and the effective value of current tests is determined.

7.2.4 SYSTEM TESTING

System testing ensures that the entire integrated software system meets requirements. It tests a configuration to ensure known and predictable results. An example of system testing is the configuration oriented system integration test. System testing is based on process descriptions and flows, emphasizing pre-driven process links and integration points.

WHITE BOX TESTING

This testing is also called as Glass box testing. In this testing, by knowing the specific functions that a product has been design to perform test can be conducted that demonstrate each function is fully operational at the same time searching for errors in each function. It is a test case design method that uses the

control structure of the procedural design to derive test cases. Basis path testing is a white box testing.

Basis path testing:

- Flow graph notation
- Kilometric complexity
- Deriving test cases
- Graph matrices Control

BLACK BOX TESTING

Black Box Testing is testing the software without any knowledge of the inner workings, structure or language of the module being tested. Black box tests, as most other kinds of tests, must be written from a definitive source document, such as specification or requirements document, such as specification or requirements document. It is a testing in which the software under test is treated, as a black box .you cannot “see” into it. The test provides inputs and responds to outputs without considering how the software works.

7.2.5 INTEGRATION TESTING

Software integration testing is the incremental integration testing of two or more integrated software components on a single platform to produce failures caused by interface defects.

The task of the integration test is to check that components or software applications, e.g. components in a software system or – one step up – software applications at the company level – interact without error.

Test ID	Test Scenario	Test Steps	Expected Results	Actual Results	Status
TU01	Check Header Navigation Works Properly	1. Go to site 2. Verify	Navigation should work smoothly	As Expected	Pass
TU02	Check Privacy Policy is configured Properly	1. Go to site 2. Verify	Privacy Document should be visible to all	As Expected	Pass
TU03	Check whether all navigations in mobile View is good.	3. Go to site 4. Verify	All Navigations are Compatible with Mobile views	As Expected	Pass

Test Results All the test cases mentioned above passed successfully. No defects encountered.

7.2.6 ACCEPTANCE TESTING

User Acceptance Testing is a critical phase of any project and requires significant participation by the end user. It also ensures that the system meets the functional requirements.

Test ID	Test Scenario	Test Steps	Test Data	Expected Results	Actual Results	Status
TU01	Check User Login with valid Data	3. Go to site 4. Enter UserName 5. Enter Password 6. Click Submit	UserName=demo Password = demo@123	User should Login into an application	As Expected	Pass
TU02	Check User Login with invalid Data	5. Go to site 6. Enter UserName 7. Enter Password 8. Click Submit	UserName = demo Password = demo123	User should not Login into an application	As Expected	Pass

Test Results All the test cases mentioned above passed successfully. No defects encountered.

CHAPTER 8

CONCLUSION

In this project we have successfully designed the web application for analysing the tweets of a particular hashtag using Opinion Mining(OM). To take advantage of both natural language and social networks relationships, a novel research branch is developing

8.1 APPLICATIONS

This project can be utilized in the following applications:

1. Social Media Monitoring

There are more than 3.5 billion active social media users; that's 45% of the world's population. Every minute users send over 500,000 Tweets and post 510,000 Facebook comments, and a large amount of these messages contain valuable business insights about how customers feel towards products, brands and services.

Sentiment analysis allows businesses to mine this data and extract the feelings that underlie social media conversations, to understand how people are talking about a given product or topic, and why.

2. Brand Monitoring

Besides social media, online conversations can take place in blogs, review websites, news websites and forum discussions. Product reviews, for instance, have become a crucial step in the buyer's journey. Consumers read at least 10

reviews before buying, and 57% only trust a business if it has a star-rating of 4 or more.

If you need to get detailed insights on different features related to your product, you should try aspect-based sentiment analysis. This will allow you to see what specific aspects of your product are being praised or criticized by customers.

3. Customer Support Analysis

Providing outstanding customer service experiences should be a priority. After all, 96% of consumers say great customer service is a key factor to choose and stay loyal to a brand.

Fortunately, sentiment analysis can help you make your customer support interactions faster and more effective.

If you run sentiment analysis on all your incoming tickets, you can easily detect the most dissatisfied customers or the most urgent issues and prioritize them above the rest. Plus, you could route tickets to the appropriate person or team in charge of dealing with them.

You can also use sentiment analysis to assess the results of your customer support strategy. Let's take this Tweet complaining about Airbnb customer support

4. Customer Feedback Analysis

Net Promoter Score (NPS) surveys are one of the most popular ways to ask for customers feedback about a product or service. Sentiment analysis of NPS surveys allows you to go beyond the numerical scores and groups (Detractors,

Promoters, Passives), as well as speed up the process and obtain more consistent results than if you were tagging these results manually.

By running aspect-based sentiment analysis on a set of open-ended NPS responses, you'll gauge sentiments regarding specific features of your product. That way, you'll find out what customers appreciate and dislike most about your product. Once your sentiment analysis process is up and running, you'll also be able to compare results with previous NPS surveys and see how sentiments toward aspects of your product have improved over time.

5. Market Research

Want to collect insights on customer feelings, experiences, and needs relating to a marketing campaign for a new product release? Sentiment analysis can help monitor online conversations about a specific marketing campaign, so you can see how it's performing.

You can also find out how customers feel about a new product. Is it already getting positive or negative feedback ahead of its release. Perhaps customers are unhappy with the pricing or would have liked to see an additional feature.

8.2. FUTURE ENHANCEMENT

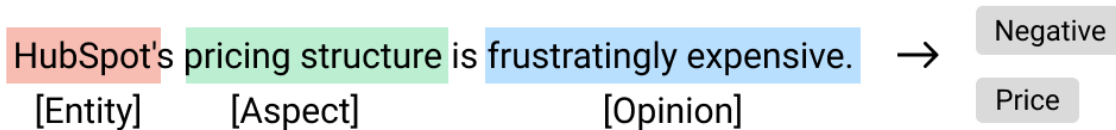

1) Emotion Detection

This sentiment analysis model detects the emotions that underlie a text. It makes associations between words and emotions like anger, happiness, frustration, etc. For example,

- 'Hubspot makes my day a lot easier :)' → Happiness
- 'Your customer service is a nightmare! Totally useless!!' → Anger

2) Aspect-based Sentiment Analysis

This type of sentiment analysis focuses on understanding the aspects or features that are being discussed in a given opinion. Product reviews, for example, are often composed of different opinions about different characteristics of a product, like Price, UX-UI, Integrations, Mobile Version, etc. Let's see some examples:

3) Intent Detection

This type of sentiment analysis tries to find an action behind a given opinion, something that the user wants to do. Identifying user intents allows you to detect valuable opportunities to help customers, such as solving an issue, making improvements on a product or deriving complaints to the correspondent areas:

- "Very frustrated right now. Instagram keeps closing when I log in. Can you help?" → Request for Assistance

Customers experiencing issues can be easily spotted thanks to sentiment analysis.

.

A.1 SAMPLE SCREENS

USER LOGIN SCREEN

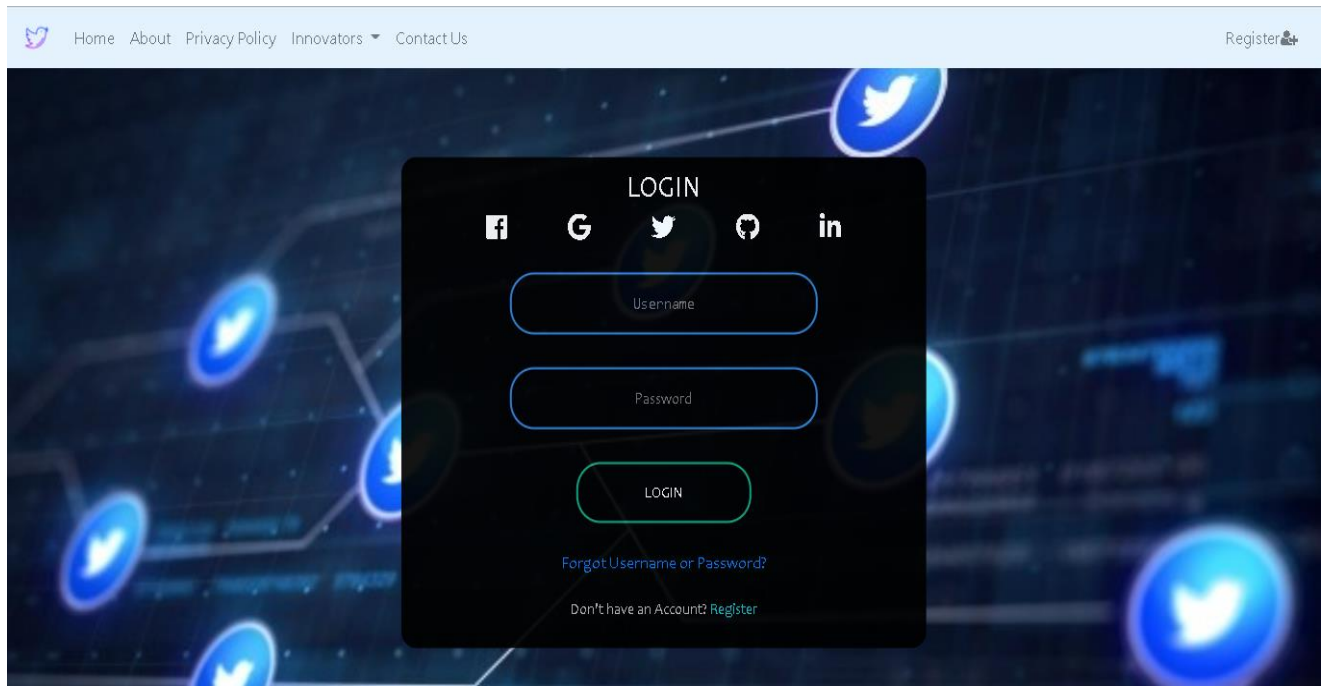

Fig A.1.1 User Login Screen

USER REGISTRATION SCREEN

The image shows a web browser displaying a user registration screen. The browser's address bar shows the URL `https://nlptweets.herokuapp.com/register#`. The page has a light blue header with a Twitter logo, navigation links (Home, About, Privacy Policy, Innovators, Contact Us), and a Login link. The main content area features a dark blue background with a network of glowing blue nodes and lines. Overlaid on this is a black registration form with the title "REGISTER". The form contains four input fields: "Username", "email", "Password", and "Confirm Password", each with a blue outline. Below these fields is a green "REGISTER" button. At the bottom of the form, there is a link that says "Already Have an Account? Login".

NATURAL LANGUAGE PROCESSING ANALYSIS WEBSITE USING PYTHON/DJANGO

K.Praveen¹, J.J.Nanthakumar², N.Nirmal Kumar³

Student, CSE, Panimalar Engineering College, Chennai, India^{1,2,3}

Abstract: Reviews act as a valuable source of information for decision making. Online e-commerce sites have provided their users to make their opinion about products and services. Huge amount of such opinions are publicly available in the form of reviews. Manufacturers, retailer as well as customers have great interest in customer reviews. Due to large number of reviews available on internet for analysis, it is not cost worthy to read these manually. To optimize this time consuming task there is a need of an automated system which provides summarized result of user sentiments. Opinion Mining (OM) is the field of study that analyzes people's sentiments or opinion from reviews or opinionated text. Opinion Mining can be viewed as a natural language processing task, the task is to develop a system that understands the people's language. Opinion Mining is a difficult task due to ambiguous nature of human languages (like English).

Keywords: Django, API, tweepy, NLP, heroku, textblob

I. INTRODUCTION

Natural Language Processing or NLP is a field of Artificial Intelligence that gives the machines the ability to read, understand and derive meaning from human languages. It is a discipline that focuses on the interaction between data science and human language, and is scaling to lots of industries. Today NLP is booming thanks to the huge improvements in the access to data and the increase in computational power, which are allowing practitioners to achieve meaningful results in areas like healthcare, media, finance and human resources, among others. In simple terms, NLP represents the automatic handling of natural human language like speech or text, and although the concept itself is fascinating, the real value behind this technology comes from the use cases.

II. EXISTING SYSTEM

Twitter, with 500 million users and million messages per day, has quickly become a valuable asset for organizations to invigilate their reputation and brands by extracting and analyzing the sentiment of the tweets by the public about their products, services market, and even about competitors highlighted that, from the social media generated opinions with the mammoth growth of the world wide web, super volumes of opinion texts in the form of tweets, reviews, blogs or any discussion groups and forums are available for data analysis, thus making the world wide web the very fast, most comprising and easily accessible medium for Opinion Mining.

III. PROPOSED SYSTEM

Imagine you just launched a new product feature and notice a sharp increase in mentions on Twitter. Are customers tweeting more because they are delighted with the new feature? Or, are they actually complaining about the feature?

Problem definition

- Going through each of these comments manually would take far too much time. You did miss out on valuable feedback that could help you instantly improve a customer's experience with the latest feature (bug issues, user experience).
- By performing analysis with NLP, you can quickly understand the tone and context of social mentions on Twitter.

Advantages:

- Opinion Mining
- Advanced Visualization for tweets
- Authentication via Different Social Media Platforms
- Exporting Tweets to Excel Sheet

Modules

- Basic Authentication
- Object Data collection
- Data Preprocessing
- Data Visualization

**Module Description:****Basic Authentication:**

The Django authentication system handles both authentication and authorization. Briefly, authentication verifies a user is who they claim to be, and authorization determines what an authenticated user is allowed to do. Here the term authentication is used to refer to both tasks.

The authentication system consists of:

- ✓ Users
- ✓ Permissions: Binary (yes/no) flags designating whether a user may perform a certain task.
- ✓ Groups: A generic way of applying labels and permissions to more than one user.
- ✓ A configurable password hashing system
- ✓ Forms and view tools for logging in users, or restricting content
- ✓ A pluggable backend system

So the user will login/register to our website in a secure manner, we have provided privacy policy to the users that how we use the data.

Object Data collection:

Real-time data collected from Twitter. The collection of data is one of the major and most important tasks of any machine learning project. Because the input we feed to the algorithms is data. So, the algorithm's efficiency and accuracy depend upon the correctness and quality of data collected. So the data should be clear as possible for better results. Depending on the hashtag entered by the user we will get the most popular and recent tweets.

Data Preprocessing:

Collection of data is one task and making that data as meaningful is another vital task. Data collected from various sources like Twitter, Facebook, etc. means those data will be in an unorganized format and there may be a lot of null values, invalid data values, and unwanted data. Cleaning all these data and replacing them with appropriate or approximate data and removing null and missing data and replacing them with some fixed alternate values are the basic steps in pre-processing of data. Even data collected may contain completely garbage values. It may not be in the exact format or the way that is meant to be. All those cases should be verified and replaced with some other alternate values to make the data meaningful and useful for further processing. Data must be kept in an organized format. So here we have used some regex expressions to clean some of the text of the tweets.

Data Visualization:

Data visualization is the process of translating information into a visual context, such as a map or graph, to make data much easier for the human brain to understand those data and get some insights from it. The main goal of data visualization is to make it easier to identify patterns, trends, and outliers in large data sets. So when the user hits analyze button on our website it will process those tweets and send back those results to the front end and the user can visualize those data based on sentiments, retweet status counts, favorite counts, etc. even the user can view individual positive tweets, negative tweets and neutral tweets then he/she can export it to excel if needed.

Software Requirements

- Windows 7 and above
- Python 3.x
- Django 3.x
- Twitter API Credentials
- Other dependencies find [here](#)

Hardware Requirements

- Hard Disk : 80GB and Above
- RAM : 4GB and Above
- Processor : Intel Core i3 and Above

Technology Used

- JavaScript, HTML5, CSS3, AJAX, JQuery.
- Django Framework
- MVC Pattern
- Tweepy, Chart.js

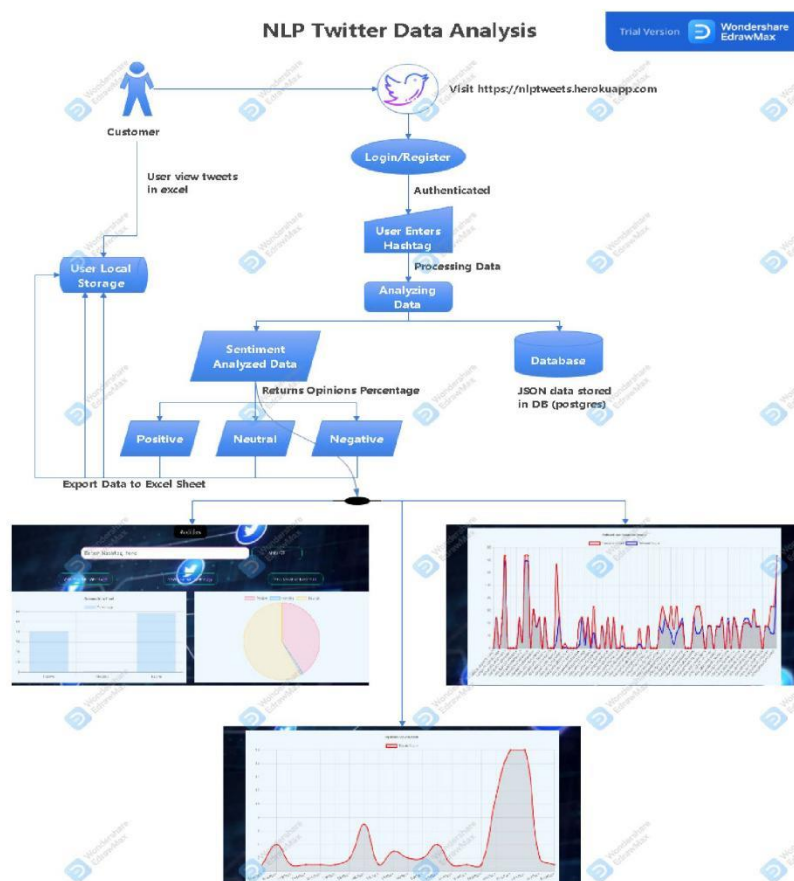

CONCLUSION:

Thus the main aim is to help business people with their product analysis based on the hashtag that they will post on Twitter. Our website has successfully tested and deployed successfully.
